Tangent Lines Guide Notes

REVIEW BASIC TERMS

CIRCLE - is the set of all points in a plane that are equidistant from a given point in the plane called the center.

RADIUS - is a segment with one end point at the center and the other end point on the circle.

CHORD - is a segment that joins two points on the circle.

DIAMETER - is a chord through the center of the circle.

SECANT - is a line contains a chord.

TANGENT - is a line in the plane of the circle that intersects the circle in exactly one point is a tangent to the circle.

POINT OF TANGENCY - is the point where the tangent line intersects the circle.

TANGENT LINES

THEOREM 1: If a line is tangent to a circle, then it is perpendicular to the radius at its outer endpoint.

Sample Problem 1

1. In the figure, SE is a radius and ET is the tangent to the circle at E. If SE = 12 cm and ET = 16 cm, how far is T from the center S?

Solution:

Since ET is the tangent to the radius at E, then they are perpendicular to each other. Hence, ΔSET is a right triangle. We then apply the Pythagorean Theorem.

\[
ST = \sqrt{SE^2 + ET^2} \\
= \sqrt{12^2 + 16^2} \\
= \sqrt{144 + 256} \\
= \sqrt{400} \\
= 20\text{cm}
\]
Tangent Lines Guide Notes

**Theorem 2:** If two tangent segments are drawn to a circle from an external point, then

A. The two segments are congruent, and

B. The angles between the segment and the line joining the external point to the center of the circle are congruent.

**Sample Problem 2**

2. The figure shows the distance from the base of the light house to a circular garden. What is the radius of the garden?

Solution:

\[
(TO)^2 + (OE)^2 = (TE)^2
\]

\[
r^2 + (24)^2 = (25)^2
\]

\[
r^2 + 576 = 625
\]

\[
r^2 = 49
\]

\[
r = 7
\]

**Theorem 3:** If a line is perpendicular to a radius of a circle at a point on the circle, then the line is tangent to the circle.

**Example 1:**

Given: \(\odot A\) with \(AB\) a radius and \(AB \perp m\) at point \(B\)

Prove: Line \(m\) is a tangent to \(\odot A\) at \(B\).

**Proof:**

<table>
<thead>
<tr>

<th>Reasons</th>
</tr>
</thead>
<tbody>
<tr>
<td>Let (C) be any point on (m) distinct</td>
<td>A line maybe named by any of its two points.</td>
</tr>
<tr>
<td>Draw (AC).</td>
<td>The line postulate</td>
</tr>
<tr>
<td>(AB \perp m) at (B).</td>
<td>Given</td>
</tr>
<tr>
<td>(\angle ABC) is a right angle.</td>
<td>Definition of perpendicularity</td>
</tr>
<tr>
<td>(\triangle ABC) is a right triangle</td>
<td>Definition right triangle</td>
</tr>
<tr>
<td>(AC &gt; AB)</td>
<td>The first Minimum Theorem</td>
</tr>
<tr>
<td>(C) is exterior of (\odot A) at (B).</td>
<td>(C) is any point except (B). If a line touches a circle at only one point, then it is a tangent to the circle.</td>
</tr>
</tbody>
</table>
Sample Problem 3:

3. Determine whether ER is tangent to $\odot P$ at E.

![Diagram of a triangle with vertices P, E, and R]

Solution:

If $\Delta PRE$ is not a right triangle, then ER is not a tangent to P at E. Apply the converse of Pythagorean Theorem to check whether $\Delta PRE$ is a right triangle.

\[
(PR)^2 = (PE)^2 + (ER)^2
\]

\[
17^2 = 8^2 + 15^2
\]

\[
289 = 289
\]

Since $(PR)^2 = (PE)^2 + (ER)^2$, $\Delta PRE$ is a right triangle. So, $\angle PER$ is a right angle, and ER is a tangent to $\odot P$ at E.

**Theorem 4:** If two circles are tangent internally or externally, their lines of centers pass through the point contact.

---

Given: $\odot A$ and $\odot B$ are tangents to $m$ at P.

Prove: AB passes through P.

Proof:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Reasons</th>
</tr>
